

Phase 6 — Origin Detection + Verification

Deployment Guide for Coolify

This guide walks you through deploying Phase 6 (Origin Detection + Verification) to your Coolify instance.

What's New in Phase 6

1. Automatic Origin IP Detection

- DNS analysis (A and AAAA records)
- Cloudflare proxy detection
- Confidence scoring (high/medium/low/unknown)
- Server IP classification (public/private/reserved/cloudflare)

2. Origin IP History

- Tracks all origin changes
- Records detection events
- Logs manual verifications

3. Manual Verification UI

- Dashboard interface for verifying origin IPs
- Add notes to verifications
- Audit log integration

4. API Endpoints

- `GET /api/dashboard/sites/{uuid}/origin/history` — View origin change history
 - `POST /api/dashboard/sites/{uuid}/origin/verify` — Manually verify an origin IP
 - `PATCH /api/dashboard/sites/{uuid}/origin/confidence` — Update confidence level
-

Prerequisites

- Phase 5 successfully deployed and running
 - Access to Coolify web interface at `https://vps.marqira.com`
 - SSH access to VPS at `187.77.136.105` (optional, for troubleshooting)
 - GitHub repo at `https://github.com/UsmanNaimed/MarQira-Pulse` with Phase 6 code pushed to `main`
-

Step 1: Verify GitHub Repository

1.1 Check that Phase 6 code is on GitHub

1. Open your web browser

2. Navigate to: `https://github.com/UsmanNaimed/MarQira-Pulse`
3. Click on the **“Code”** tab
4. Verify you see the latest commit message mentioning **“Phase 6”** or **“Origin Detection”**
5. Click on `apps/api/app/Services/` and verify you see `OriginDetector.php`

What you should see: The file `OriginDetector.php` listed in the Services directory.

Step 2: Deploy API Changes

2.1 Trigger API rebuild in Coolify

1. Open Coolify at `https://vps.marqira.com`
2. Log in with your credentials
3. Navigate to **Projects → MarQira Pulse**
4. Click on the **“marqira-api”** resource (or whatever you named your Laravel API service)
5. Look for the **“Deploy”** or **“Redeploy”** button (usually in the top right)
6. Click **“Deploy”**

What happens: Coolify will:

- Pull the latest code from your GitHub `main` branch
- Rebuild the Docker image
- Deploy the new container

This will take 2-5 minutes. You'll see build logs streaming in real-time.

2.2 Run database migration

After the API container is running, you need to run the new migration for `origin_ip_history` table.

Option A: Via Coolify UI (if your Coolify supports shell access)

1. In the `marqira-api` service page, look for **“Execute Command”** or **“Shell”** button
2. Click it to open a terminal into the running container
3. Run:

```
bash
```

```
php artisan migrate --force
```

4. You should see:

```
Migrating: 2024_01_01_000010_create_origin_ip_history_table
```

```
Migrated: 2024_01_01_000010_create_origin_ip_history_table
```

Option B: Via SSH

1. SSH into your VPS:

```
bash
```

```
ssh root@187.77.136.105
```

2. Find the API container name:

```
bash
```

```
docker ps | grep marqira-api
```

Look for a container name like `marqira-api-1` or `marqira_api_1`.

3. Run the migration inside the container:

```
bash
```

```
docker exec -it <container_name> php artisan migrate --force
```

Replace `<container_name>` with the actual name from step 2.

What you should see: Migration success message with the new table created.

2.3 Verify API health

1. In your browser, navigate to: `https://api.marqira.com/api/health`
2. You should see JSON like:

```
json
{
  "status": "ok",
  "service": "MarQira Pulse API",
  "timestamp": "2026-08-17T..."
}
```

If you see this: API is running successfully.

If you see an error page: Check the build logs in Coolify for errors.

Step 3: Deploy Dashboard Changes

3.1 Trigger Dashboard rebuild

1. In Coolify, go back to **Projects** → **MarQira Pulse**
2. Click on the **“marqira-dashboard”** resource
3. Click **“Deploy”** or **“Redeploy”**

What happens: Coolify will:

- Pull the latest React/TypeScript code
- Run `npm install` and `npm run build`
- Deploy the new static build

This will take 1-3 minutes.

3.2 Verify Dashboard

1. Open `https://app.marqira.com` in your browser
2. Log in with your account
3. Navigate to **Websites**
4. Click on `olympianwatertestingschools.com` (or any enrolled site)
5. Click the **“Network”** tab

What you should see:

- **Server Information** section (Server IP, hostname, software)
- **Origin IP Detection** section with:
 - Origin IP address
 - Detection source
 - Confidence badge (high/medium/low/unknown) with color coding
 - Verified status
- **Manually Verify Origin IP** form (if not already verified)

If the verification form appears: You can test it by:

1. Entering the origin IP (or confirming the detected one)
2. Adding optional notes
3. Clicking **“Verify Origin IP”**
4. Page should reload and show the origin as verified

Step 4: Test Origin Detection

4.1 Wait for next heartbeat

The origin detection runs automatically on every heartbeat from the WordPress plugin. The plugin sends heartbeats every ~10 minutes.

To verify origin detection is working:

1. In the dashboard, go to **Websites** → Click on a site
2. Go to the **“Network”** tab
3. Check the **“Origin IP”** field — it should be populated (if `null`, wait for next heartbeat)
4. Check the **“Detection source”** — e.g., `dns_a_match`, `server_addr`, etc.
5. Check the **“Confidence”** badge — should be `high`, `medium`, `low`, or `unknown`

4.2 Test manual verification

1. On the **Network** tab, scroll to **“Manually Verify Origin IP”**
2. If the detected origin is correct, you can verify it by:
 - Entering the IP (or leaving it as pre-filled)
 - Adding a note like “Confirmed via hosting panel”
 - Clicking **“Verify Origin IP”**
3. The page will reload
4. The **“Verified”** pill should now show a green checkmark
5. The verification form should disappear (only unverified origins show the form)

4.3 Check origin history

Origin changes are logged in the `origin_ip_history` table. To view them via API:

1. Get the site UUID from the URL: `https://app.marqira.com/websites/<uuid>`
2. In a new tab, visit:

```
https://api.marqira.com/api/dashboard/sites/<uuid>/origin/history
```

 (You may need to be logged into the dashboard for the session cookie to authenticate)

What you should see: JSON array of history entries showing detected, verified, and `confidence_changed` events.

Step 5: Verify Database Tables

5.1 Check `origin_ip_history` table

Connect to PostgreSQL and verify the new table exists:

Via SSH:

```
ssh root@187.77.136.105
docker ps | grep postgres
docker exec -it <postgres_container> psql -U marqira_user -d marqira_db
```

In psql:

```
\dt origin_ip_history
SELECT * FROM origin_ip_history LIMIT 5;
```

What you should see:

- Table `origin_ip_history` exists
- Rows appear after sites send heartbeats (may be empty if no heartbeats yet)

To exit psql:

```
\q
```

Step 6: Troubleshooting

Problem: Migration fails with “table already exists”

Solution: The migration may have run before. Check:

```
SELECT * FROM migrations WHERE migration LIKE '%origin_ip_history%';
```

If it's listed, the migration already ran. If not, run:

```
php artisan migrate:refresh --step=1
```

Problem: Origin IP stays null

Possible causes:

1. WordPress site hasn't sent a heartbeat yet (wait ~10 minutes)
2. DNS lookup failing for the domain
3. `SERVER_ADDR` not available from WordPress

Check:

- Go to **Connection History** tab and verify recent heartbeats
- Check the heartbeat payload for `server_ip` value
- Review Laravel logs for DNS errors:

```
bash
```

```
docker exec -it <api_container> tail -n 50 storage/logs/laravel.log
```

Problem: Dashboard shows old UI without verification form

Solutions:

1. **Hard refresh** the browser: `Ctrl+Shift+R` (Windows/Linux) or `Cmd+Shift+R` (Mac)
2. Clear browser cache and reload

3. Check Coolify build logs for dashboard deployment errors
4. Verify `WebsiteDetail.tsx` was updated in GitHub

Problem: “Verification failed” error when clicking Verify

Check:

1. Browser console for JavaScript errors (F12 → Console tab)
2. Network tab for API response (F12 → Network → filter by “verify”)
3. Laravel logs for validation errors:

```
bash
```

```
docker logs <api_container_name> --tail=100
```

Step 7: Rollback (If Needed)

If Phase 6 breaks something critically:

7.1 Revert GitHub repo

```
cd /path/to/MarQira-Pulse # on your local machine
git log --oneline
git revert <phase_6_commit_hash>
git push
```

7.2 Redeploy in Coolify

Follow Step 2.1 and Step 3.1 again — Coolify will pull the reverted code.

7.3 Rollback migration

If you need to undo the `origin_ip_history` table:

```
docker exec -it <api_container> php artisan migrate:rollback --step=1
```

Step 8: Post-Deployment Checklist

- [] API health check returns 200 OK
- [] Dashboard loads without errors
- [] Migration `origin_ip_history` ran successfully
- [] Network tab shows Origin IP Detection section
- [] Manual verification form appears for unverified origins
- [] Confidence badge displays with correct color
- [] Origin history API endpoint returns data
- [] Audit log shows `site.origin_verified` events after manual verification
- [] No errors in Laravel logs
- [] No errors in browser console

Next Steps

- **Phase 7:** Private plugin updates at `updates.marqira.com`
 - **Phase 8:** n8n API endpoints
 - **Phase 9:** Origin bypass proxy
 - **Phase 10:** Commercial SaaS (subscriptions, plans, billing)
-

Support

If you encounter issues not covered in this guide:

1. Check Laravel logs: `docker logs <api_container> --tail=200`
 2. Check PostgreSQL for data: `SELECT * FROM origin_ip_history LIMIT 10;`
 3. Review Coolify build logs for deployment errors
 4. Verify GitHub has the latest code: `https://github.com/UsmanNaimed/MarQira-Pulse/commits/main`
-

Deployed: [Date you deployed Phase 6]

API: `https://api.marqira.com`

Dashboard: `https://app.marqira.com`

VPS: `187.77.136.105` (`vps.marqira.com`)
